

SUMMARY

The instrument for the allergies' detection is a cutaneous kit which has a main body, with a sharp edge (5) around its circumference at the lower surface (4). At least one cavity (21) or hollow space is coaxial to the body (1) for a multi-point needle (8). The outer circumference of the body is bonded to the inner edge of a flexible ring (16), in turn held by a rigid support (17) at its outer edge. The whole of the lower surface of the kit is shrouded by a blister. The cavity and the surrounding space (14) is filled with at least one allergenic substance. The instrument can contain three bodies with their needle assemblies.
